APPROVAL SHEET

This thesis entitled THE EFFECTS OF HIGH DOSES AND DOMINANT LETHALITY OF MONOSODIUM GLUTAMATE ON MALE DOGS (CANIS DOMESTICA), prepared and submitted by Ms. Salvacion E. Hata in partial fulfillment of the requirements for the degree of Master of Science in Biology has been examined and is recommended for acceptance and approval for ORAL EXAMINATION.

ABSTRACT

The administration of monosodium glutamate to the dogs by different routes and in different concentrations affects blood pressure, pulse rate, and respiratory rate. The dogs given intravenous doses of monosodium glutamate was most sensitive to its presence, although the response offered was not as great as those offered by the dogs with subcutaneously and orally administered MSG. The dogs responded to the substance in different pattern. The first 20 minutes after the dose was given, showed blood pressure and pulse rate building to its peak. This was a prelude to salivation, vomiting, and sometimes urination. As salivation and vomiting subsided, there was a decline in the amplitude of the responses, almost nearing the baseline data. The effect on respiratory rate was very erratic without establishing a definite pattern. As the concentration of the dose of MSG was increased, the blood pressure and pulse rate increased with it. The respiratory rate in turn was inversely affected by the increase. Effects on the body organs depended on the routes of administration. In intravenously injected dogs, the heart was bloated with clotted blood inside which were not observed in the dogs given MSG through a different route. The lungs of the dogs showed varying degrees of collapse and the livers showed cyanotic patches. The dilation of the pupil of the eye of the test animals was also affected. Increase in concentration of the dose of MSG weakened the corneal and knee reflexes of the animal. A general analysis of these results showed that the lowest tolerance level to MSG was exhibited by the dogs given intravenous doses and the highest tolerance level was exhibited by the dogs given oral feeding of MSG. The administration of 50% sugar solution following a lethal dose of MSG appeared to diminish the intensity of the effects induced by monosodium glutamate.

ACKNOWLEDGMENTS

Deepest thanks and gratitude go to Dr. Letecia G. Cabrera, who provided assistance and made valuable suggestions and corrections on the manuscript.

Most sincere appreciation is extended to CDCAS Dean, Dr. Carmen R. Fortunato, for her encouragement; to Dr. Teresita Tiu, Chairman, Biochemistry-Physiology Dept., CDCM, and to Engr. Rossano E. Hate of the Physics Dept., CDCAS, for their valuable interpretations of the data; to Mr. Peregrino Dulay and Mr. Dominador Dulay, for their technical assistance during the whole duration of the experiment, and most especially to the President and Members of the Board, CDCI, for their financial assistance and for allowing the use of CDCM-Physiology laboratory and its facilities.

Dr. Montana C. Saniel, Dean, Graduate School, USC, Mr. Cristobal Plateros, and Mr. Antonio Batomalaque will always be remembered for their expertise. Special thanks go to Ms. Susan Cañete of USC Graduate School, and to Mrs. Colly S. Abellar of CDCAS, for their immeasurable help.

Deepest gratitude, regards and thanks go to her parents, brothers, sisters and Nard, who gave all the much needed encouragement and moral support during the bleakest part of the experiment.

The researcher wishes to express her deepest appreciation and thanks to the many persons who in one way or the other make the experiment possible and a reality.
